# **Declaration**

I, Amy Lai , confirm that the work presented in this thesis is my own. Where information has been derived from other sources, I confirm that this has been indicated in the work.

# Abstract

The dominant degradation pathways of nitrocellulose (NC) were investigated, using quantum mechanics (QM) methods to probe the primary denitration routes, followed by key secondary reactions. The polymer structure was truncated in order to facilitate density functional theory (DFT) studies into the mechanistic details of denitration at individual nitrate sites. Comparison of monomer, dimer and trimer units of the polymer using quantum theory of atoms in molecules (QTAIM) topology analysis of interaction sites, analysis of the electrostatic potential (ESP) and charges showed that the most suitable model for study of the decomposition reactions was  $\beta$ -glucopyranose monomer, bi-capped with methoxy groups. The model was nitrated at the C2 position, to mimic the most stable nitration site [1]. The primary thermolytic and hydrolytic denitration routes were explored using transition state (TS) searches and potential energy surface (PES) scans. It was found that the thermolytic behaviour of the NC denitration step matched the energy profile of other nitrate esters [2]. Protonation at the bridging oxygen site of the nitrate was found to be the most likely to lead to denitration. It was not possible to isolate a TS for the hydrolytic reaction, though a number of coordination schemes were tested. Secondary processes following initial denitration were examined. Ethyl nitrate was used as a test system before extension to the monomer. Different reaction pathways for decomposition, with forward propagation of the evolved species to the reaction step, revealed that  $\text{HNO}_2$  was the most likely cause for the experimentally observed autocatalytic rate of degradation.

# Impact Statement

This study examines the degradation properties of NC, shedding light on the mechanistic details of decomposition that are yet currently either unknown, or are unclear with contradictory views in existing literature. NC is used in a massive variety of products, with utilisation in household, industrial, military and medicinal applications.

Improved understanding of the fundamental chemistry in the degradation of NC could benefit in the following key impact areas:

## **Knowledge & collective benefit**

- Broaden understanding and depth of knowledge in the area of NC degradation, with the view to validate or reject conflicting schemes in literature.
- Improve conservation procedures for existing and legacy NC products, such as cinematographic film, artworks and historical munitions with better understanding of the handling procedures for these aged products.

## **Environmental**

Design next generation NC products more environmentally friendly, in terms of durability and recycle-ability.

Improve and clean up industrial processes for more environmentally benign production process.

Design appropriate NC disposal methods, other than the existing harsh chemical or incineration treatment, with opportunity to feed back into other processes, such as the production of fertiliser.

## **Safety**

Guidelines on safety and usage could be refined based on detailed knowledge of the degradation reactions, instead of current guidelines based on more crude, aggregate experimental

observations.

**Industrial & Commercial**

More adaptability in the production of NC and its formulation into products, in the case that the variety of source cellulose feedstock changes due to supply chain issues.

Streamline industrial processes to specific reactivity requirements, based on detailed mechanistic considerations, leading to cost saving.

**Innovation**

Create new products, not limited by previous assumptions about the shelf life and reactivity.

Facilitate the design of products for applications that were previously not known that the material was suitable for.
